Resumo	This study aimed to investigate the discriminative capacity of IDCP-2 factors to identify people with suicide risk. Moreover, we are providing a suicide total score for IDCP-2. Participated 346 people aged between 18 and

72 years who responded to ASIQ, IDCP-2, and PID-5. We divided participants into three groups: low-risk group moderate-risk and high-risk group. We conducted mean comparisons, linear regression analysis, and ROC curve verification. The IDCP-2 factors were able to discriminate between the groups, with the high-risk presenting the highest means. The regression indicated Self-devaluation and Hopelessness as variables with a significant single contribution in explaining suicidal behavior. Suicide risk indicators demonstrated adequate performance in identifying people according to the risk group. Our findings indicate that the IDCP-2 factors can discriminate groups of people according to suicidal behavior. Besides, the index developed showed sensitivity in the identification of people who reported attempted suicide. How to cite this article: Gonçalves, A.P., Machado, G.M., Pianowski, G., Carvalho, L.F.
